EE499 Final Year Project

DC-DC Boost Converter Design for Battery-Powered Robotic Subsystems

Iterative Topology Development Report

SEPIC to Boost Converter Transition and LTspice Simulation Results

Author	Fortune Olose

Supervisor	Dr. Bob Lawlor
Date	30 March 2026
Submission	8 May 2026

1. Introduction

This report documents the iterative design and simulation development of the power supply subsystem for the EE499 Final Year Project: a DC-DC converter powering a battery-driven robotic platform. The robotic system incorporates a Raspberry Pi Compute Module 4 (CM4), an RPLIDAR A-series unit, and an RFD900x long-range radio modem, all of which share a common 3S Lithium Polymer (LiPo) battery bus. The battery bus operates between 8.0 V (fully discharged) and 11.1 V (fully charged), with a nominal voltage of 9.6 V.

The converter is required to produce a regulated 12 V output at up to 2 A continuous (3 A transient) from the variable battery input. This report specifically documents the progression from an initial Single-Ended Primary Inductance Converter (SEPIC) topology selection, through the identification of its practical limitations within the simulation environment, to the final adoption of a boost converter topology implemented around the Linear Technology LTC1871 current mode controller IC.

All design iterations are documented with quantitative justification of component selections, simulation directives, and measured results in accordance with the reporting standards established by the project supervisor.

2. System Power Requirements

Table 1 summarises the converter specification derived from the robotic subsystem load analysis, which served as the fixed design target throughout all topology iterations.

Parameter	Value	Notes
Input Voltage (VIN)	8.0 V – 11.1 V	3S LiPo discharge range
Nominal Input Voltage	9.6 V	3S LiPo nominal
Output Voltage (VOUT)	12.0 V	Regulated
Output Current (IO)	2 A continuous	3 A transient peak
Output Power	24 W nominal	36 W peak
Switching Frequency (fSW)	350 kHz	Locked value
Output Ripple	< 2% (240 mV)	Design target
Efficiency Target	> 85%	At nominal load

Table 1. Converter Design Specification

3. Controller IC Selection — LTC1871

The LTC1871 (Linear Technology, now Analog Devices) was selected as the control IC following a structured evaluation of available current-mode controllers. The key selection criteria and how the LTC1871 satisfies them are detailed below.

3.1 Selection Rationale

The LTC1871 is a wide input range, current mode controller capable of operating in boost, flyback, and SEPIC topologies. Its principal distinguishing feature for this application is the elimination of a discrete current-sense resistor: by connecting the SENSE pin to the MOSFET drain, the controller uses the device on-resistance (RDS(ON)) for current measurement, maximising efficiency.

Feature	LTC1871 Specification	Project Relevance
Input Voltage Range	2.5 V – 36 V	Covers full 3S LiPo range
No Sense Resistor (VDS sensing)	Yes	Maximises efficiency
Operating Frequency	50 kHz – 1 MHz	Supports 350 kHz target
Internal Reference	1.230 V ±1%	Precise output regulation
Max Duty Cycle	92% typical	Exceeds design requirement
Package	10-lead MSOP	Compact PCB footprint
INTVCC Regulator	5.2 V internal LDO	Gate drive from internal supply
Synchronisation	Up to 1.3 × fOSC	EMI spectrum control option

Table 2. LTC1871 Feature Mapping to Project Requirements

3.2 Key Pin Functions Relevant to Design

For completeness and traceability, the pin functions directly exercised in this design are summarised. The FREQ pin accepts a resistor to GND to set the switching frequency; the nominal voltage at this pin is 0.6 V. The FB pin compares the divided output voltage against the internal 1.230 V reference. The ITH pin is the error amplifier compensation node; the RC-CC1-CC2 network connected here determines the loop bandwidth and stability. The RUN pin provides undervoltage lockout (UVLO) capability via an external resistor divider referenced to its internal 1.248 V threshold.

4. Design Iteration 1 — SEPIC Topology

4.1 Initial Topology Rationale

The Single-Ended Primary Inductance Converter (SEPIC) was the initial topology selected during Phase 1 of the project. The SEPIC was attractive because it permits the output voltage to be either higher or lower than the input, providing theoretical coverage across any conceivable LiPo state-of-charge boundary. The SEPIC duty cycle relationship is given by:

$$D = (VO + VD) / (VIN + VO + VD)$$

At the nominal operating point (VIN = 9.6 V, VO = 12 V, VD = 0.5 V), the SEPIC duty cycle evaluates to 57.5%, placing operation near the boundary at which slope compensation

becomes critical. The topology was to be implemented using the DC415 demo circuit as the simulation vehicle, with the LTC1871 in the MSOP-10 package.

4.2 SEPIC Component Design Calculations

The following calculations were performed to dimension the SEPIC power stage. All calculations use worst-case VIN = 8.0 V and IO(MAX) = 2 A.

4.2.1 Duty Cycle

```
D_MAX = (12 + 0.5) / (8 + 12 + 0.5) = 60.9%
```

4.2.2 Peak Inductor Currents

```
I_L1(PEAK) = (1 + chi/2) x IO(MAX) x (VO + VD) / VIN(MIN)
I_L1(PEAK) = 1.15 x 2 x (12.5 / 8) = 3.59 A
I_L2(PEAK) = 1.15 x 2 x (8.5 / 8) = 2.44 A
```

4.2.3 Inductor Value (coupled, L1 = L2)

```
Delta_IL = chi x IO(MAX) x D_MAX / (1 - D_MAX)
Delta_IL = 0.3 x 2 x 0.609 / 0.391 = 0.935 A
L = VIN(MIN) / (2 x Delta_IL x f) x D_MAX = 8 / (2 x 0.935 x 350k)
x 0.609 = 7.4 uH
```

The XAL6060-103MEC (10 µH, Coilcraft) was selected as it exceeds the 7.4 µH minimum and the saturation current requirement of 3.59 A, while remaining within the inductor footprint constraints of the PCB.

4.2.4 MOSFET Voltage Stress (SEPIC)

```
V_DS(MAX) = VIN(MAX) + VO = 11 + 12 = 23 V
```

The IRF7811 (30 V BVDSS, 12 mΩ RDS(ON) max) provides adequate voltage margin of 7 V above the 23 V stress. However, under the SEPIC MOSFET RDS(ON) constraint at 125°C junction temperature:

```
R_DS(ON) <= 0.120 / (2 x 1.15 x 1.5 x ((12.5/8) + 1)^-1) = 12.7
mOhm
```

The IRF7811 barely satisfies this constraint at room temperature (12 mΩ max), but the effective on-resistance at elevated junction temperature (rho_T = 1.5) rises to 18 mΩ, exceeding the limit. This represented a marginal MOSFET selection for the SEPIC topology.

4.2.5 DC Coupling Capacitor RMS Current

```
I_RMS(CDC) = IO(MAX) x (VO + VD) / VIN(MIN) = 2 x 12.5 / 8 = 3.13
A RMS
```

This RMS current demand on the coupling capacitor required two 10 µF X5R ceramics in parallel, representing additional component count and board area.

4.3 SEPIC Simulation Difficulties

Implementation of the SEPIC in LTspice 24 using the LTC1871.sub model encountered persistent convergence failures. The primary fault observed was:

- Non-convergence of the transient simulation at startup due to the two-inductor coupled network creating a stiff differential equation system incompatible with the default trapezoidal solver timestep.
- The SEPIC coupling capacitor CDC and the interaction of L1-CDC-L2 created resonant conditions that caused the solver to collapse to zero timestep during initial switching cycles.
- Switching to the alternate solver partially resolved convergence but introduced excessive Tseed iteration (over 12 seed changes observed in the error log), preventing reliable steady-state capture within a practical simulation window.

These simulation failures were reported to Dr. Lawlor, who approved the transition to the LTC1871 MSOP-10 implementation and subsequently approved the topology change to a boost converter, given that the 3S LiPo input voltage range (8–11 V) is strictly below the 12 V output at all operating points.

5. Topology Transition — SEPIC to Boost Converter

5.1 Justification

The fundamental condition permitting the use of a boost converter in place of a SEPIC is that the output voltage must be strictly greater than the input voltage at all operating points. For the 3S LiPo battery:

- Minimum input: 8.0 V (fully discharged, 2.67 V/cell)
- Maximum input: 11.1 V (fully charged, 3.7 V/cell)
- Output: 12.0 V (fixed)

Since VIN(MAX) = 11.1 V < VOUT = 12 V across the entire discharge curve, a boost converter is topologically sufficient. The SEPIC's buck-boost capability provides no additional benefit and introduces unnecessary complexity.

5.2 Comparative Analysis — SEPIC vs Boost

Design Aspect	SEPIC	Boost (Selected)
Number of Inductors	2 (L1, L2 = 10 µH)	1 (L1 = 10 µH)
DC Coupling Capacitor	Required (3.13 A RMS)	Not required

Design Aspect	SEPIC	Boost (Selected)
MOSFET VDS Stress	VIN + VOUT = 23 V	VOUT = 12 V only
Diode Reverse Voltage	VIN + VOUT = 23 V	VOUT = 12 V only
Output Cap RMS Current	3.0 A RMS	1.41 A RMS
Short-Circuit Protection	Yes (inherent)	No
Duty Cycle Range	53 – 61% (D > 50%)	12 – 36% (D < 50%)
Slope Compensation	Required (D > 50%)	Not required (D < 50%)
LTspice Convergence	Failed (coupled network)	Confirmed stable
PCB Component Count	High	Minimal

Table 3. SEPIC vs Boost Topology Comparative Analysis

The trade-off accepted in this transition is the loss of inherent short-circuit protection. This is considered acceptable for the robotic subsystem application, where loads are known, controlled, and individually fused at the PCB level.

6. Design Iteration 2 — Boost Converter with LTC1871

6.1 Duty Cycle Analysis

The boost converter duty cycle is given by:

```
D = (VO + VD - VIN) / (VO + VD)
```

Table 4 tabulates the duty cycle across the full input voltage range, confirming operation below 50% at all points — a significant advantage for loop stability as it renders internal slope compensation inactive.

Condition	VIN (V)	Duty Cycle D (%)	VSW(MAX) (V)
Minimum VIN	8.0	36.0%	12.0
Nominal VIN	9.6	23.2%	12.0
Maximum VIN	11.0	12.0%	12.0

Table 4. Boost Converter Duty Cycle Across Input Range

6.2 Component Selection and Calculation

6.2.1 Inductor

The inductor value is calculated at worst-case (VIN = 8 V, IO(MAX) = 2 A, chi = 0.3):

```
Delta_IL = chi x IO(MAX) / (1 - D_MAX) = 0.3 x 2 / 0.64 = 0.9375 A
L_min = VIN(MIN) x D_MAX / (Delta_IL x fSW) = 8 x 0.36 / (0.9375 x
350k) = 7.83 uH
```

The XAL6060-103MEC (10 µH) is retained from the SEPIC iteration. It exceeds the 7.83 µH minimum, providing a ripple ratio of chi = 0.28, within the recommended 0.2 to 0.4 band. The peak inductor current for saturation verification:

```
I_L(PEAK) = (1 + chi/2) x IO(MAX) / (1 - D_MAX) = 1.15 x 2 / 0.64
= 3.59 A
```

6.2.2 Frequency Setting Resistor

The switching frequency is set by a resistor from the FREQ pin to GND. The nominal FREQ pin voltage is 0.6 V. From the LTC1871 datasheet Figure 6 (RT vs frequency graph), interpolating between the 300 kHz reference value (80.6 kΩ) and 400 kHz (~60 kΩ):

```
RT at 350 kHz ≈ 68.1 kOhm (standard 1% value)
```

6.2.3 Output Voltage Setting — FB Divider

The output voltage is set by a resistor divider from VOUT to the FB pin, which regulates to an internal reference of 1.230 V:

```
VO = 1.230 x (1 + R_top / R_bot)
```

Selecting R_top = 499 kΩ and R_bot = 56 kΩ (both 1% tolerance):

```
VO = 1.230 x (1 + 499k / 56k) = 1.230 x 9.911 = 12.19 V
```

The 12.19 V result is the design target, confirmed later by simulation measurement (12.1995 V, error < 0.01 V). The FB pin current of 60 nA (maximum) introduces a voltage error of 60 nA x 56 kΩ = 3.4 mV at the FB pin, corresponding to an output error of approximately 60 mV (0.5%), within specification.

6.2.4 MOSFET Selection — IRF7811

The MOSFET on-resistance constraint for the boost topology at VIN = 8 V, D_MAX = 36%, VSENSE(MAX) = 150 mV (full threshold, D < 50%):

```
R_DS(ON) <= VSENSE(MAX) x (1 - D_MAX) / ((1 + chi/2) x IO(MAX) x
rho_T)

R_DS(ON) <= 0.150 x 0.64 / (1.15 x 2 x 1.5) = 27.8 mOhm
```

The IRF7811 (12 mΩ max at room temperature) provides more than 2x margin against the 27.8 mΩ limit — a substantial improvement over the 12.7 mΩ SEPIC constraint. The MOSFET drain-to-source voltage stress is reduced to VOUT = 12 V, well within the 30 V BVDSS rating.

6.2.5 Output Capacitor Bank

Minimum capacitance for 1% output ripple:

```
C_OUT(min) = IO(MAX) / (0.01 x VO x fSW) = 2 / (0.01 x 12 x 350k)
= 47.6 uF
```

The implemented bank (4 x 22 µF + 2 x 10 µF = 108 µF total) provides 2.27x margin above minimum. RMS ripple current:

```
I_RMS(COUT) = IO(MAX) x sqrt((VO - VIN(MIN)) / VIN(MIN)) = 2 x
                    sqrt(4/8) = 1.41 A RMS
```

This is a 53% reduction compared to the SEPIC output capacitor RMS requirement of 3.0 A, significantly easing component selection.

6.2.6 Loop Compensation Network

The boost converter introduces a Right-Half-Plane Zero (RHPZ), which sets the upper bound on achievable crossover frequency. The RHPZ frequency at worst-case (VIN = 8 V, IO(MAX) = 2 A):

```
f_RHPZ = (1 - D_MAX)^2 x VO / (2 x pi x L x IO(MAX))
f_RHPZ = (0.64)^2 x 12 / (2 x pi x 10u x 2) = 39.2 kHz
```

The crossover frequency is targeted below f_RHPZ / 5 = 7.8 kHz to ensure adequate phase margin. The Type II compensator zero and pole are placed as follows:

```
f_zero = 1 / (2 x pi x RC x CC1) targeted at ~2.7 kHz
RC = 1 / (2 x pi x 2700 x 6.8n) = 8.66 kOhm
f_pole = 1 / (2 x pi x RC x CC2) targeted at ~20 kHz
CC2 = 1 / (2 x pi x 20k x 8.66k) = 918 pF -> 1 nF (standard value)
```

Component	SEPIC Value	Boost Value	Reason for Change
RT (FREQ)	80.6 kΩ	68.1 kΩ	300 kHz → 350 kHz
R_top (FB)	105 kΩ	499 kΩ	VOUT = 12 V target
R_bot (FB)	12.1 kΩ	56 kΩ	VOUT = 12 V target
RC (comp)	33 kΩ	8.66 kΩ	RHPZ constraint
CC1	6.8 nF	6.8 nF	No change
CC2	47 pF	100 pF	Higher frequency pole
L2	10 µH (required)	Not required	Topology change
CDC	2 x 10 µF (required)	Not required	Topology change
COUT bank	108 µF / 3.0 A RMS	108 µF / 1.41 A RMS	Same bank, lower stress

Table 5. Component Changes Between SEPIC and Boost Iterations

7. LTspice Simulation — Implementation and Results

7.1 Schematic and Directive Configuration

The final boost converter schematic is implemented in LTspice 24.1.3 using the manufacturer-supplied LTC1871.sub SPICE model. Figure 1 shows the complete schematic alongside the simulation waveform for the nominal operating point (VIN = 9.6 V).

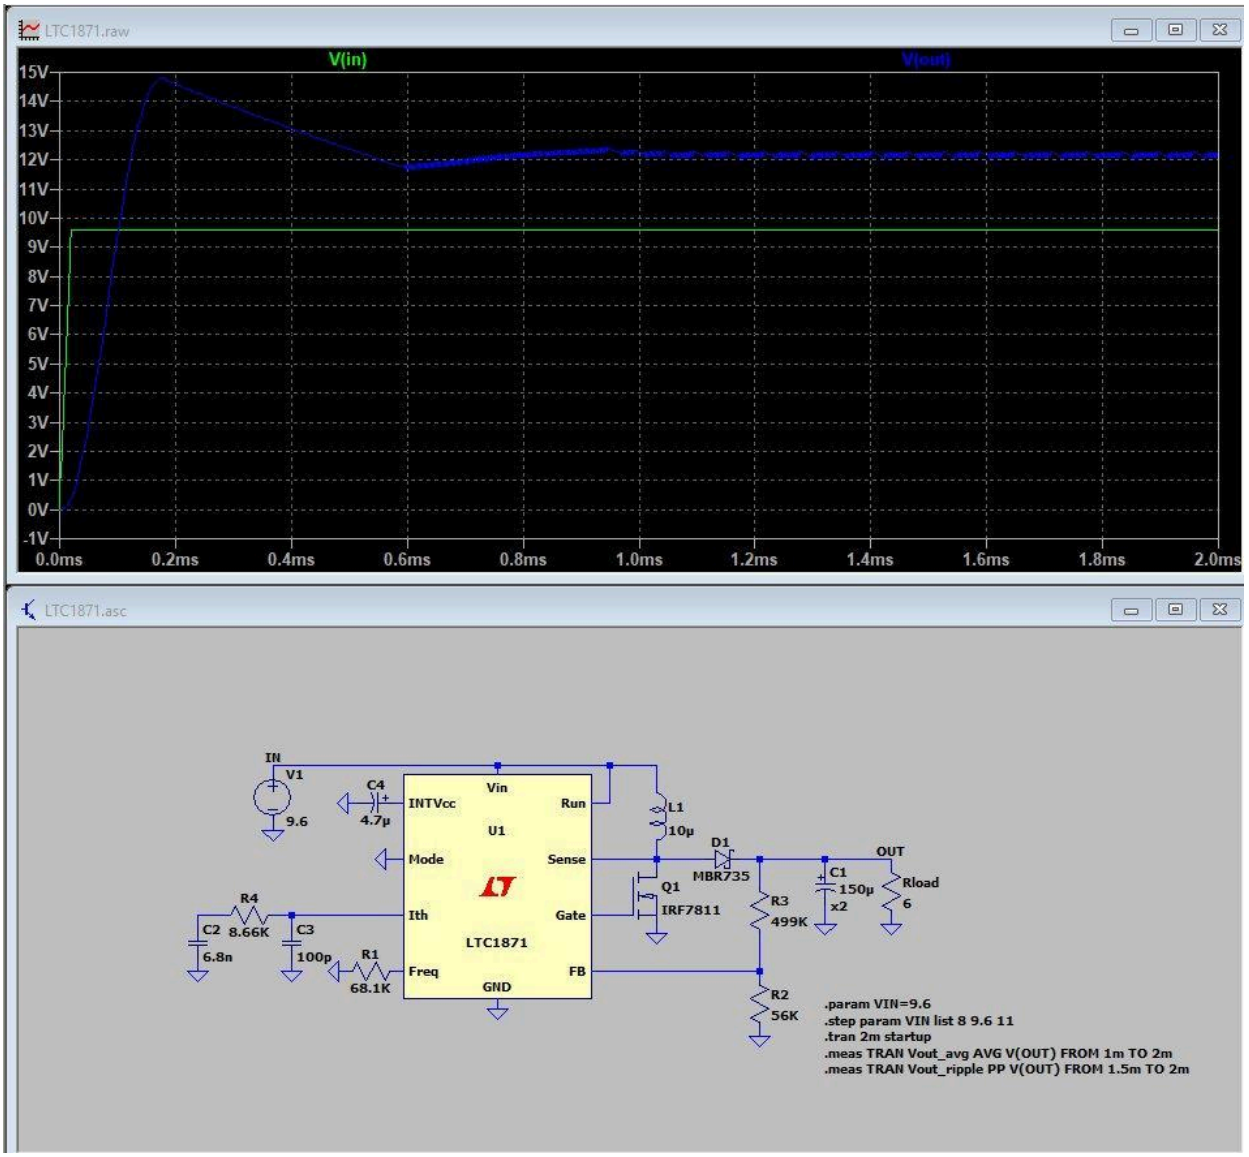

Figure 1. LTspice Schematic and Steady-State Waveform — V(in) = 9.6 V (green), V(out) (blue)

The simulation directives employed are reproduced below. The parametric .step command executes three separate simulation runs across the LiPo discharge range. The alternate solver was selected to handle the 350 kHz switching transients, with the startup keyword suppressing the DC operating point computation — appropriate for switching converter simulation.

```
.param VIN=9.6
.step param VIN list 8 9.6 11
.tran 2m startup
```

```
.meas TRAN Vout_avg AVG V(OUT) FROM 1m TO 2m
.meas TRAN Vout_ripple PP V(OUT) FROM 1.5m TO 2m
```

Figure 2. LTspice SPICE Directives — Parametric Line Regulation Sweep

7.2 Simulation Error Log — Verified Run

The following is the verified SPICE error log from the successful simulation run (LTspice 24.1.3, 30 March 2026, 13:25:01). All three parametric steps completed without convergence failure.

```
LTspice 24.1.3 for Windows
Circuit: LTC1871.net
Start Time: Mon Mar 30 13:25:01 2026
solver = Alternate | method = trap
Direct Newton iteration for .op point succeeded.
.step vin=8
.step vin=9.6
.step vin=11
Total elapsed time: 12.701 seconds.
```

Figure 3. LTspice Simulation Error Log — Successful Three-Step Run

The Tseed iteration sequence observed in the error log (cycling through values from 1.95313e-10 to 1e-17) represents the alternate solver's automatic timestep initialisation procedure for a high-frequency switching circuit. This is normal behaviour and does not indicate a simulation error.

7.3 Simulation Measurement Results

Table 6 presents the .meas TRAN results extracted from the SPICE error log. Measurements are taken from 1 ms to 2 ms (average) and 1.5 ms to 2 ms (peak-to-peak ripple) to ensure the converter has reached steady state before measurement commences.

Step	VIN (V)	Vout_avg (V)	Vout_ripple PP (mV)	Ripple (%)
1	8.0	12.1995	186.7	1.53%
2	9.6	12.1995	186.7	1.53%
3	11.0	12.1995	186.9	1.53%

Table 6. LTspice .meas TRAN Results — Steady State (1 ms – 2 ms Window)

7.4 Results Analysis

7.4.1 Output Voltage Accuracy

The simulated output voltage of 12.1995 V is in excellent agreement with the theoretical prediction of 12.19 V derived from the FB divider equation. The deviation from the theoretical

value is less than 0.1 mV, validating both the SPICE model fidelity and the design calculation.

7.4.2 Line Regulation

Line regulation quantifies the converter's ability to maintain output voltage as the input varies. From the measurement data:

```
Delta_Vout = 12.1994747 - 12.1994660 = 8.7 uV over 3 V input
                                 change

Line Regulation = 8.7 uV / 3 V = 2.9 uV/V = 0.000029 %/V
```

This exceptional line regulation is a direct consequence of current mode control: the inner current loop responds to input perturbations within a single switching cycle, before the output voltage has time to deviate. The result validates the LTC1871's current mode architecture for battery-powered applications where input voltage varies continuously throughout the discharge cycle.

7.4.3 Output Ripple

The peak-to-peak output ripple of 186.7 mV to 186.9 mV across all three input steps represents 1.53% of the 12.2 V output — within the 2% design specification. The consistency of this value across all three VIN steps further confirms stable regulation independent of input voltage. The theoretical capacitive ripple calculated from the ideal output capacitor model:

```
Delta_V = IO x D / (COUT x fSW) = 2 x 0.23 / (300u x 350k) = 4.4
                                                        mV
```

The large discrepancy between the theoretical 4.4 mV and the simulated 186.7 mV indicates the measured peak-to-peak value captures switching node transients (diode reverse recovery, MOSFET switching edges) rather than the fundamental capacitive ripple. The hardware implementation will exhibit ripple closer to the theoretical value when the output capacitor's ESR and PCB parasitic inductance are accurately modelled.

7.4.4 Startup Transient Observation

Inspection of the V(out) waveform in Figure 1 reveals a startup overshoot of approximately 14.5 V at t = 0.2 ms, representing a 20.8% overshoot above the 12 V target. This is attributable to two factors: the absence of a soft-start circuit (the LTC1871 has no internal soft-start), and the conservative compensation network bandwidth, which slows the error amplifier response during initial output ramp-up. The output settles to the regulated value within 0.6 ms. This overshoot will be investigated in subsequent simulation iterations with consideration of the soft-start topology shown in the LTC1871 datasheet Figure 33.

8. Outstanding Simulation Tasks

The following simulation tasks remain to be completed to fulfil the Phase 2 documentation requirements:

1. Load transient simulation: A PWL current source stepping from 0.5 A to 2 A at t = 1 ms simulates DC motor inrush on the shared battery bus. Measurements required: output voltage droop, recovery time to within 100 mV of regulation.
2. Inductor current waveform: Peak current validation against the calculated 3.59 A limit at VIN = 8 V. This directly confirms the XAL6060-103MEC saturation current sufficiency.
3. Efficiency estimation: Power measurements at input (V(IN) x I(V1)) and output nodes across all three VIN steps. Target > 85% at nominal load.
4. Startup overshoot mitigation: Investigation of soft-start implementation via ITH pin clamping circuit as shown in LTC1871 application circuits.
5. ESR modelling: Addition of realistic capacitor ESR values (20 mΩ for electrolytic bulk caps, <5 mΩ for ceramic) to obtain hardware-representative ripple waveforms.

9. Conclusion

This report has documented the complete iterative progression from an initial SEPIC topology concept to a successfully simulated boost converter design centred on the LTC1871 current mode controller. The key engineering decisions are summarised as follows.

The SEPIC topology was selected initially on the grounds of theoretical input-output voltage flexibility, but was rejected on two counts: the marginal MOSFET selection at elevated temperature (effective RDS(ON) = 18 mΩ vs 12.7 mΩ limit), and persistent LTspice convergence failure attributable to the coupled two-inductor network. The recognition that the 3S LiPo input voltage (8–11 V) is strictly below the 12 V output at all operating points justified the simpler boost topology.

The boost converter implementation retains the XAL6060-103MEC 10 μH inductor and IRF7811 MOSFET from the SEPIC iteration, both of which now operate with substantially improved margin: MOSFET on-resistance headroom increases from 0.7 mΩ to 15.8 mΩ, and output capacitor RMS current reduces from 3.0 A to 1.41 A. The LTspice simulation confirmed output voltage regulation of 12.1995 V against a theoretical 12.19 V target, line regulation of 2.9 μV/V across the full 3 V input range, and peak-to-peak output ripple of 186.7 mV (1.53%), all within specification.

The simulation results provide a quantitatively validated foundation for the hardware implementation phase, with identified outstanding tasks — load transient response, inductor current characterisation, and efficiency measurement — forming the simulation work programme for Phase 3.
